ABSTRACT

Nowadays technology development grows fast. Many appliances become small but have high efficiency. The device which can measure digital signal is called Oscilloscope. This device can only use at a time, we cannot get old results back. It also cannot perform multi-channels signal measurement simultaneously. With these limits using Oscilloscope for logic analysis is impractical because the analysis need to work with many signals and statistical results.

Logic Analyzer is a device that can do all tasks need for logic analysis. It can get data back and perform multi - channels signal measurement. But this device is very expensive. So this project is developed to serve all conditions and also named Logic Analyzer. It can measure 16 signals in the same time and have a memory to store data which can restore it back.
